Quantitative analysis of superoxide anion ($O_2^{\cdot-}$) has increasing importance considering its potential damages to organism. Herein, a novel Mn-superoxide dismutase (MnSOD) mimics, silica-manganous phosphate ($SiO_2-Mn_3(PO_4)_2$) nanoparticles, were designed and synthesized by surface self-assembly processes that occur on the surface of silica-phytic acid (SiO_2-PA) nanoparticles. The composite nanoparticles were characterized by fourier transform infrared spectroscopy (FTIR), transmission electron microscopy (TEM), scanning electronic microscopy (SEM), electron diffraction pattern, energy dispersive spectroscopy (EDS) and elemental mapping. Then the electrochemical measurements of $O_2^{\cdot-}$ based on the incorporation of $SiO_2-Mn_3(PO_4)_2$ onto the surface of electrodes were performed, and some satisfactory results were obtained. This is the first report that manganous phosphate ($Mn_3(PO_4)_2$) nanoparticles with shape-controlled, but not multilayer sheets, were utilized for $O_2^{\cdot-}$ detection. The surface self-assembly technology we proposed will offer the ideal material to construct more types biosensor and catalytic system for its nanosized effect.

Active reactive oxygen species (ROS) containing oxygen atoms are the substances with strong oxidizing ability, which can cause or aggravate cancer, cardiovascular diseases, asthma, cataract, ulcer disease, Alzheimer's disease, Parkinson's disease and other diseases. $O_2^{\cdot-}$, the critical important part of the so-called ROS, is implicated in many physiological and pathological processes¹⁻³. Under normal physiological conditions, $O_2^{\cdot-}$ maintains the relatively balanced level *in vivo*. Once the cell produces excessive $O_2^{\cdot-}$ in response to external stimulus or pathological changes, it will lead to etiology of aging, cancer, and progressive neurodegenerative diseases such as Parkinson's disease. Thus, real-time analysis and detection of $O_2^{\cdot-}$ have great significance. A variety of approaches have been tried to measure $O_2^{\cdot-}$ concentration, such as electron spin resonance⁴⁻⁶, spectrophotometry⁷, chemiluminescence⁸, colorimetry^{9,10}, chromatograph^{11,12} and fluorescence¹³⁻¹⁵. However, these methods cost much and usually occupy too much space. In comparison with other methods, the electrochemical method has recently attracted a great deal of attention owing to its advantages including high sensitivity, low detection limit, simplicity, direct, real-time detection and so on.

Up to date, the commonly used electrochemical enzyme sensors are fabricated by immobilizing superoxide dismutase (SOD) and cytochrome (cyt c) onto the electrode surface. However, the enzymatic $O_2^{\cdot-}$ sensors are easily affected by pH and temperature changes, which limit their practical applications due to the poor stability of nature enzyme. Nanozymes, possessing enzymatic activities with nanostructure, have attracted particular attention as emerging natural enzyme mimics, they offer the possibility of lowered cost, improved stability, and excellent recyclability¹⁶⁻¹⁸. Meanwhile, bionic concept has gained more and more attention¹⁹⁻²¹. Mn-superoxide dismutase (MnSOD) mimics, manganous phosphate ($Mn_3(PO_4)_2$), manganous pyrophosphate ($Mn_2P_2O_7$) and manganese (II) complexes are usually used to fabricate biosensors for $O_2^{\cdot-}$ detection^{22,23}. Cabelli have studied the antioxidant mechanism of aggregated $Mn_3(PO_4)_2$ particles in organic vivo²⁴. Li used DNA as a template to

produce Mn₃(PO₄)₂ nanosheets and decorated this biomimetic enzyme onto the electrode surface for sensitive *in-situ* detection of O₂^{•−}²⁵. However, the intrinsic drawbacks of DNA, including high cost, instability, and storage difficulty, may limit their widely applications of electrochemical sensors. Dai also reported the high efficient catalysis of Mn₂P₂O₇, which was used as a SOD mimic for O₂^{•−} detection²⁶. There is a serious problem in dealing with the preparation of these reported MnSOD mimics. It is that the conventional synthesized MnSOD mimics that reported in the previous literatures have multilayer sheet structure with uncontrolled shape, thickness and size. This approach will bring resources waste and low catalytic efficiency. We wonder how it is possible to utilize surface self-assembly technology and nanotechnology to construct a more efficient MnSOD mimic for promoting analytical properties.

In this paper, SiO₂-Mn₃(PO₄)₂ NPs were synthesized by surface self-assembly processes that occur on the surface of SiO₂-phytic acid (SiO₂-PA). To the best of our knowledge, there are no reports employing surface coating technique to immobilize Mn₃(PO₄)₂ onto the surface of NPs for O₂^{•−} detection. The SiO₂-Mn₃(PO₄)₂ NPs have many advantages, like controllable shape with nanoscale, high specific surface area than that of nano-sheet structure, low cost, simple preparation process, non-toxic, and so on. This novel MnSOD mimic we prepared is utilized to fabricate biosensors, and the electrochemical measurements of O₂^{•−} based on the incorporation of SiO₂-Mn₃(PO₄)₂ onto the electrodes surface are performed.

Results and Discussion

Figure 1 showed the fourier transform infrared (FTIR) spectroscopy of SiO₂ NPs (a) and SiO₂-PA NPs (b). For curve (a), the appearance of characteristic peak at 1106 cm^{−1} and 957 cm^{−1} were attributed to the O-Si-O bonds stretching vibration, indicating that SiO₂ NPs were successfully synthesized²⁷. Compared with unmodified SiO₂ NPs, the SiO₂-PA NPs illustrated three extra peaks at 2928, 1552 and 695 cm^{−1}, which should be attributed to -C-NH₂ stretching, symmetric -NH₂ stretching, and the bending vibrations of -NH in APTES, respectively²⁸. The results indicated that APTES was successfully modified onto the surface of SiO₂ NPs²⁹. More importantly, an adsorption peak at 1092 cm^{−1} was observed due to the overlap of the characteristic peak of phosphate group (PO₄^{3−}) and the peak of asymmetric O-Si-O stretching³⁰. The results confirmed that the SiO₂ NPs were successfully modified by APTES and PA.

Figure 3. TEM images of (A) SiO₂ NPs, (B) SiO₂-PA NPs, (C) SiO₂-Mn₃(PO₄)₂ NPs, and (D) EDS spectrum and elemental mapping of SiO₂-Mn₃(PO₄)₂ NPs.

As shown in Fig. 2a, the Zeta potential of SiO₂ surface was -38.5 mV, which was attributed to many -OH and other oxygen-containing groups that present in the SiO₂ NPs surface. When modified with APTES, the Zeta potential of APTES-SiO₂ NPs increased to $+22.3$ mV that due to the amine groups on the surface of the particles (Fig. 2b). However, the Zeta potential measurements for SiO₂-PA NPs (Fig. 2c) showed a negative surface charge that owing to the six phosphate groups of PA. When Mn²⁺ ions in solution were self-assembled onto the surface of SiO₂-PA NPs, the zeta potential increased to -14.1 mV. The change of Zeta potential indicated that SiO₂-Mn₃(PO₄)₂ NPs were successfully synthesized by self-assembly technology based on the electrostatic interaction that between Mn²⁺ ions and the phosphate groups³¹.

The TEM and SEM images were also employed to further confirm the formation of SiO₂-Mn₃(PO₄)₂ NPs. Figure 3A revealed that the spherical SiO₂ NPs were obtained with the average particle size of 75 nm. After surface self-assembly of PA and Mn²⁺ sequentially, the two sizes of SiO₂-PA NPs and SiO₂-Mn₃(PO₄)₂ NPs showed a slight increase (Fig. 3B,C), respectively. Furthermore, the electron diffraction pattern displayed an amorphous diffraction pattern of Mn₃(PO₄)₂ that deposited on the surface of silica (see the inset from Fig. 3C). And the corresponding elemental mapping of oxygen (O), silicon (Si), phosphorus (P), and manganese (Mn) from the SiO₂-Mn₃(PO₄)₂ NPs were indicated in Fig. 3D. The energy dispersive spectroscopy (EDS) of SiO₂-Mn₃(PO₄)₂ NPs showed that the different atomic percentages were 85.32% (O), 13.10% (Si), 1.47% (P), and 0.11% (Mn), respectively. It can be concluded that Mn₃(PO₄)₂ was firmly coated onto the outer surface of the SiO₂-PA NPs. Mn₃(PO₄)₂ layer has little effect on the size growth of SiO₂ NPs because it was only monolayer of Mn₃(PO₄)₂ molecular that self-assembled onto the outer surface of SiO₂ NPs based on the electrostatic interaction. Here, the stability of Mn₃(PO₄)₂ supported on SiO₂ NPs was evaluated by Zeta potential measurement after three weeks of storage. As was shown in Figure S1, the Zeta potential of the SiO₂-Mn₃(PO₄)₂ NPs had almost no change after three weeks of storage, indicating the Mn₃(PO₄)₂ NPs have long-term stability. SEM images were also used to investigate the surface texture change after Mn₃(PO₄)₂ coating on SiO₂ NPs, and the particle size of Mn₃(PO₄)₂. Figure S2 showed the SEM images of the SiO₂ NPs, SiO₂-PA NPs and SiO₂-Mn₃(PO₄)₂ NPs, respectively. It can be observed from the SEM results that the samples with Mn₃(PO₄)₂ coating can remain its original spherical morphology. Meantime, it can also be seen in this figure that particle size of the samples showed a slight increase after Mn₃(PO₄)₂ coating on SiO₂ NPs, which was in consistency with the results obtained by TEM images as showed

Figure 4. (A) Schematic illustration of the formation of $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2$ NPs: (a) Amino-modified process of SiO_2 NPs, (b) Phytic acid modified process of $\text{SiO}_2\text{-NH}_2$ NPs, and (c) Self-assembled of $\text{Mn}_3(\text{PO}_4)_2$ on the outer surface of $\text{SiO}_2\text{-PA}$ NPs, (B) Schematic diagram for the construction of the biosensor.

Figure 5. (A) Cyclic voltammograms (CVs) of (a) bare GCE, (b) $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2/\text{GCE}$, (c) $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2/\text{MWCNTs}/\text{GCE}$, (d) $\text{Mn}_3(\text{PO}_4)_2/\text{MWCNTs}/\text{GCE}$, and (e) MWCNTs/GCE , (B) CVs of $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2/\text{MWCNTs}/\text{GCE}$ in the presence (a) and absence (b) of $1.0 \mu\text{mol L}^{-1} \text{O}_2^{\cdot-}$ in PBS (pH 7.4), scan rate: $100 \text{ mV}\cdot\text{s}^{-1}$.

in Fig. 3. Figure 4A illustrated the synthesis process of $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2$ NPs. The formational mechanism of this biomimetic enzyme could be explained as follows: After dropping into MnSO_4 solution, PO_4^{3-} ions, derived from the surface of $\text{SiO}_2\text{-PA}$ NPs, were in combination with Mn^{2+} ions by electrostatic interaction to form $\text{Mn}_3(\text{PO}_4)_2$. When the PO_4^{3-} ions were consumed, the monolayer of $\text{Mn}_3(\text{PO}_4)_2$ molecular was self-assembly on the outer surface of $\text{SiO}_2\text{-PA}$ NPs with controllable morphology. In addition, only aggregated $\text{Mn}_3(\text{PO}_4)_2$ particles were observed in the absence of SiO_2 NPs with the same reaction conditions (Supplementary Figure S3).

A schematic drawing of the stepwise construction process of modified glassy carbon electrode (GCE) was described in Fig. 4B. The electrochemical properties of the $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2/\text{Multi-walled carbon nanotubes (MWCNTs)}/\text{GCE}$ were investigated by cyclic voltammetry (CV) and Electrochemical Impedance Spectroscopy (EIS)^{32–35} (Supplementary Figure S4). Figure 5A displayed that all fabrication process of $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2/\text{MWCNTs}/\text{GCE}$ were carried out by CV in nitrogen saturated phosphate buffered solution (PBS) at a scan rate of $100 \text{ mV}\cdot\text{s}^{-1}$. In the working potential range of 0–0.9 V, there was no electrochemical signal can be observed at the bare GCE (curve a). In contrast, the $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2/\text{GCE}$ exhibited a pair of weakly redox peaks (curve b). When the MWCNTs/GCE was modified with $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2$ NPs, the oxidation-reduction peaks were more obviously observed (curve c) that due to the excellent electronic conductivity of MWCNTs (Supplementary Figure S5), and the sensitivity of this biosensor was largely improved³⁶. Moreover, the peak currents of $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2/\text{MWCNTs}/\text{GCE}$ (curve c) were much larger than that of $\text{Mn}_3(\text{PO}_4)_2/\text{MWCNTs}/\text{GCE}$ (curve d).

Figure 6. (A) Typical amperometric curve recorded at 0.484 V in PBS (pH 7.4) for $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2/\text{MWCNTs}/\text{GCE}$. From 0.03 to 0.21 μM , the $\text{O}_2^{\cdot-}$ concentration of each adding step was 0.03 μM , from 0.15 to 3.6 μM , each adding step was 0.15 μM , (B) Linear calibration plot of the response current vs the $\text{O}_2^{\cdot-}$ concentration.

Results demonstrated that the electro-catalytic effect of $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2$ was much higher than that of $\text{Mn}_3(\text{PO}_4)_2$ aggregated particles. It can be attributed to that the nanosized $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2$ possessed high specific surface area. As a result, it will help improve the catalytic efficiency of $\text{O}_2^{\cdot-}$ in the electrolyte. When the bare GCE was only modified with MWCNTs, the background current was more clearly observed (curve e).

To study the catalysis effect of the $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2$ NPs, the biosensor in PBS and PBS of containing 1.0 $\mu\text{mol L}^{-1}$ $\text{O}_2^{\cdot-}$ were measured by CV, respectively. As shown in Fig. 5B, in the PBS containing of 1.0 $\mu\text{mol L}^{-1}$ $\text{O}_2^{\cdot-}$ (curve a), both anodic and cathodic peak currents that corresponding to the redox reaction of in PBS (curve b) clearly increased that can be attributed to the oxidation and reduction of $\text{O}_2^{\cdot-}$, respectively³⁷. According to the previous reports^{38,39}, $\text{O}_2^{\cdot-}$ was converted into O_2 and H_2O_2 during the disproportionation reaction that $\text{O}_2^{\cdot-}$ was catalyzed by Mn^{2+} in PBS. In the anodic process, $\text{O}_2^{\cdot-}$ was oxidized to O_2 by the oxidation effect of MnO_2^+ , while MnO_2^+ was reduced to Mn^{2+} . On the contrary, Mn^{2+} was oxidized to MnO_2^+ in the cathodic process. As demonstrated above, the $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2/\text{MWCNTs}/\text{GCE}$ can be applied to detect $\text{O}_2^{\cdot-}$ by measuring the oxidation or reduction currents because of the high efficient catalysis of $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2$. To further prove this proposed mechanism/reaction, X-ray photoelectron spectroscopy (XPS) analysis was carried out to analyze the composition and chemical configuration of the $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2$ NPs before and after electrocatalysis process. More details about the XPS spectra of Mn 2p were presented in Figure S6.

The typical current-time plot of $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2/\text{MWCNTs}/\text{GCE}$ at the applied potential of 0.484 V upon successive additions of $\text{O}_2^{\cdot-}$ was provided in Fig. 6A. In this experiment, while being stirred, $\text{O}_2^{\cdot-}$ solution was added once per 50 seconds. With the injection of $\text{O}_2^{\cdot-}$, the response of this biosensor rapidly achieved 95% of the steady-state current within 2.9 s (Supplementary Figure S7). The $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2/\text{MWCNTs}/\text{GCE}$ showed a wide linear range from 0.03 to 0.21 μM and 0.15 to 3.6 μM with the correlation coefficient of 0.9966 and 0.9959, respectively. The relation of the oxidation peak current vs the concentration of $\text{O}_2^{\cdot-}$ was linear with a detection limit of 0.0175 μM ($S/N = 3$). The biosensor exhibited more excellent performance than some $\text{O}_2^{\cdot-}$ biosensors that reported by the previous papers using different electrode materials, such as SOD, $\text{Mn}_3(\text{PO}_4)_2$, and $\text{Mn}_2\text{P}_2\text{O}_7$ (Supplementary Table 1). The corresponding calibration curves for $\text{O}_2^{\cdot-}$ were depicted in Fig. 6B. The linear equations were $i (\mu\text{A}) = 0.00418 - 0.1358c (\mu\text{M})$ and $i (\mu\text{A}) = -0.01932 - 0.1263c (\mu\text{M})$, respectively. The biosensor was applied to the detection of $\text{O}_2^{\cdot-}$ and displayed excellent electrochemical behavior.

To verify the applicability of $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2$ NPs in detection of $\text{O}_2^{\cdot-}$, Xanthine/Xanthine Oxidase (XAN/XOD) was selected to generate $\text{O}_2^{\cdot-}$ (Supplementary Figure S8). In addition, the response of $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2/\text{MWCNTs}/\text{GCE}$ toward $\text{O}_2^{\cdot-}$ generated by XAN/XOD was investigated by amperometric measurements⁴⁰. As shown in Figure S9, with successive additions of XAN to the solution, a stepwise increase of the current response was observed.

To evaluate the anti-interference performance of detecting $\text{O}_2^{\cdot-}$, the biosensor was examined by successive additions of $\text{O}_2^{\cdot-}$ and interfering substances into a 0.1 M PBS at 0.484 V. Figure 7A indicated that there were obviously current responses of the biosensor during the addition of 1.0 μM $\text{O}_2^{\cdot-}$, while no obviously current response could be observed with the addition of the interferences. With the sequential addition of 5.0 μM Cys, 5.0 μM DA, 10 μM H_2O_2 , 10 μM UA and 10 μM AA, the detection current showed changes of 14%, 2.7%, 8.2%, 5.4% and 4.1% with comparison of 1.0 μM $\text{O}_2^{\cdot-}$, respectively (Fig. 7B). Figure S10 displayed the amperometric response of the $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2/\text{MWCNTs}/\text{GCE}$ by successive additions of 2.0 μM 18-crown-6 once per 50 seconds. Results demonstrated that this biosensor can eliminate the interference and show an excellent selectivity for detection of $\text{O}_2^{\cdot-}$. To verify the stability, the biosensor was monitored after being stored for three weeks in a refrigerator. Figure 7C indicated that the current response was no apparent decrease, which was much longer than those obtained for enzyme-based $\text{O}_2^{\cdot-}$ biosensors^{41–44}. In order to investigate the binding firmness of $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2$ NPs decorated onto the MWCNTs/GCE electrode, the reuse ability of the $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2/\text{MWCNTs}/\text{GCE}$ electrode was tested. Figure S11 displayed the CV curves of the biosensor for 20 cycles, which showed almost overlap curves, indicating the biosensor we prepared had a good cycle stability that can attributed to the good binding state of the $\text{SiO}_2\text{-Mn}_3(\text{PO}_4)_2$ NPs and the MWCNTs/GCE electrode.

Figure 7. (A) Interference test of SiO₂-Mn₃(PO₄)₂/MWCNTs/GCE, (B) The relative response in PBS (pH = 7.4) at 1.0 μM O₂^{·-}, 5.0 μM Cys, 5.0 μM DA, 10 μM H₂O₂, 10 μM UA and 10 μM AA, (C) CVs of SiO₂-Mn₃(PO₄)₂/MWCNTs/GCE, (a) Freshly prepared, and (b) after fifteen days in 0.1 M PBS, Scan rate was 100 mV·s⁻¹, and (D) Amperometric response of the SiO₂-Mn₃(PO₄)₂/MWCNTs/GCE in the (a) presence, and (b) absence of HeLa cells upon sequential additions of PMA to 0.1 M PBS at 0.484 V.

Real-time detection performance of the biomimetic enzyme sensor has also been monitored by detecting O₂^{·-} released from the HeLa cells. The amperometric responses of the biosensor were obtained at applied potentials of 0.484 V versus Ag/AgCl in 2 mL 0.1 M PBS (pH 7.4) containing 0.5×10^5 cells·mL⁻¹. After the injection of 4 μg mL⁻¹ phorbol 12-myristate 13-acetate (PMA), which was reported to generate O₂^{·-} from live cells⁴⁵, the current gradually increased at SiO₂-Mn₃(PO₄)₂/MWCNTs modified electrode. In this work, PMA was used as a stimulant for the cell to exude O₂^{·-}^{46,47}. Figure 7D indicated that the strong current signal (0.01457 μA, curve a) was caused by O₂^{·-} released from the HeLa cells, considering that SiO₂-Mn₃(PO₄)₂ could selectively decomposes O₂^{·-}. According to the above linear relationship, the O₂^{·-} concentration of 0.0765 μM was calculated. Thence, the amount of O₂^{·-} releasing from per 10⁵ cells was calculated to be 0.153 nmol. Meanwhile, in the absence of the HeLa cells and the presence of the treatment of PMA, no obvious current response can be seen on the screen (curve b). To test the effectiveness of this technology, the biomimetic enzyme sensor has also been used to detect the concentration of O₂^{·-} in plasma (Supplementary Figure S12).

Conclusion

In this case, the SiO₂-Mn₃(PO₄)₂ NPs, synthesized *via* self-assembly technique and nanotechnology, were applied in a biomimetic enzyme biosensor for the detection of O₂^{·-}. Results revealed that SiO₂-Mn₃(PO₄)₂/MWCNTs/GCE showed high electrocatalytic activity toward O₂^{·-}, lower detection limit and wide detection range. Furthermore, the biosensor that assembled under optimal conditions exhibited high selectivity of O₂^{·-} in the presence of related interference, such as H₂O₂, UA, AA, DA and Cys. Meanwhile, the long-term stability and good reproducibility of this biomimetic enzyme biosensor were proved. Compared with the Mn₃(PO₄)₂ multilayer sheets, the modified GCE of SiO₂-Mn₃(PO₄)₂ with high specific surface area exhibited more excellent analytical performance. Consequently, the biomimetic enzyme-free sensor was successfully applied to detecting O₂^{·-} that released from live cells, which holds a great promising platform for the reliable monitoring of major diseases in future.

Methods

Materials. Tetraethyl orthosilicate (TEOS) was purchased from Sinopharm Chemical Reagent Co. Ltd. Cetyltrimethylammonium bromide (CTAB) was obtained from Shanghai Lingfeng Chemical Reagent Co. Ltd. (3-Aminopropyl) triethoxysilane (APTES), phytic acid (PA, 70 wt%) solution and phytic acid sodium salt hydrate

were received from Aladdin Chemistry Co. Ltd (Shanghai, China). Potassium phosphate tribasic trihydrate ($K_3PO_4 \cdot 3H_2O$), manganese sulfate monohydrate ($MnSO_4 \cdot H_2O$) and dimethyl sulfoxide (DMSO) were obtained from Sinopharm Chemical Reagent Co. Ltd. Potassium superoxide (KO_2) was purchased from Alfa Aesar. Multi-walled carbon nanotubes (MWCNTs) was purchased from Shenzhen Nanotech Port Co. Ltd. Triton X-100, nafion (5 wt% solution in lower aliphatic alcohol), 18-crown-6, phorbol 12-myristate 13-acetate (PMA), dopamine (DA), cysteine (Cys), ascorbic acid (AA) and uric acid (UA) were acquired from Aladdin Sigma-Aldrich Co. (USA). Hydrogen peroxide (H_2O_2 , 30%) was received from Beijing Chemical Works (China). Phosphate buffer solution (PBS) was obtained by dissolving 8.0 g NaCl, 0.2 g KCl, 1.44 g NaH_2PO_4 and 0.24 g KH_2PO_4 in 1000 mL double-distilled water.

Apparatus. The morphologies of the samples were recorded by transmission electron microscopy (TEM) and high-resolution transmission electron microscopy (HITACHI H-7650, Japan). Scanning electron microscope (SEM) images were obtained by a Scanning electron microscope (JSM-6300, Japan). XPS measurements were performed on a Thermo ESCALAB 250 using a monochromic Al X-ray source (1486.6 eV). All the electrochemicals data were measured by CHI 760D electrochemical workstation (Shanghai Chenhua, China). Fourier transform infrared (FTIR) spectra of the SiO_2 NPs and SiO_2 -PA NPs were obtained from a VARIAN Cary 5000 Fourier transform infrared spectrophotometer (VARIAN, USA). Surface potential of the samples was performed by Zeta potential analyzer (Malvern Instruments ZS90). All experiments were carried out using a three-electrode cell equipped, which consisted of a platinum electrode, saturated calomel electrode (SCE) and working electrode.

Culture of Cells. The HeLa cells were cultured in Dulbecco's Modified Eagle's medium (DMEM) containing 10% fetal bovine serum (FBS), 100 units mL^{-1} penicillin, and 100 $\mu g \cdot mL^{-1}$ streptomycin at 37 °C. Then, the HeLa cells were centrifuged for the electrochemical experiments. Real sample measurements were performed by the addition of 100 $\mu g \cdot mL^{-1}$ PMA in PBS containing 50 mM glucose.

Preparation of SiO_2 - $Mn_3(PO_4)_2$ NPs. Firstly, SiO_2 NPs were synthesized by the reverse microemulsion method as reported previously by Bagwe⁴⁸. In a typical synthesis, triton X-100 (10.62 g), hexanol (9.6 mL) and cyclohexane (45 mL) were mixed in a 100 mL round-bottomed flask under stirring for 10 min, and then water (2.88 mL) was added to the mixture at room temperature. After being stirred for 0.5 h, $NH_3 \cdot H_2O$ (600 μL) and TEOS (1200 μL) were dropped into the above clear solution, respectively. Next, the mixture was allowed to stir for a further 24 h at room temperature. The resulting NPs were collected by centrifugation and dried at 60 °C under vacuum condition for 24 h. Then, the modified process of SiO_2 was briefly described as follows: SiO_2 NPs (0.05 g) was dissolved in double-distilled water (20 mL), and TEOS (100 μL) was added to the SiO_2 suspension with continuously stirring for 30 min at room temperature⁴⁹. Then, the SiO_2 - NH_2 NPs were obtained by feeding appropriate amount of APTES. After stirring for 30 min, 120 μL of PA/PA sodium salt hydrate buffer solution (pH = 7) was injected into the above solution with continues stirring for 24 h. The resulting NPs were washed with alcohol and double-distilled water. Finally, the SiO_2 -PA NPs were redispersed in water (10 mL), and then $MnSO_4$ aqueous solution (10 mL, 12 mM) was injected to the round-bottomed flask containing the SiO_2 -PA NPs under constant stirring for 1 h at 60 °C. After completion of the reaction, the obtained products were collected by centrifugation, washed with double-distilled water, and dried in a vacuum oven at 60 °C for 24 h.

Fabrication of SiO_2 - $Mn_3(PO_4)_2$ /MWCNTs/GCE. Firstly, MWCNTs (8.0 μL , 2.5 $mg \cdot mL^{-1}$) were cast onto the electrode surface and dried at room temperature. After that, SiO_2 - $Mn_3(PO_4)_2$ (8.0 $mg \cdot mL^{-1}$) and 2.5% Nafion with the volumetric ratio of 1:1 were mixed, and 8.0 μL of above solution was dropped onto the surface of MWCNTs/GCE. After drying in air, the SiO_2 - $Mn_3(PO_4)_2$ /MWCNTs/GCE was obtained. During the experimental period, the modified electrodes were stored at 4 °C until use.

Generation of superoxide anion. A stable $O_2^{\cdot -}$ solution was prepared by dispersing KO_2 to DMSO (containing 18-crown-6). In accordance with the molar absorptivity of $O_2^{\cdot -}$ in DMSO, the concentration of $O_2^{\cdot -}$ was monitored by recording the absorbance of ferricytochrome c spectrophotometrically at 550 nm⁵⁰. In particular, spectrophotometric measurement of the amount of ferricytochrome c that reduced by $O_2^{\cdot -}$ referred to the following reaction: cytochrome c (Fe^{III}) + $O_2^{\cdot -}$ = ferrocyanochrome c (Fe^{II}) + O_2 , in which ferrocyanochrome c exhibits a strong absorbance at 550 nm⁵¹. The linear relationship of the absorbance vs the ferrocyanochrome c concentration was depicted in Figure S13. The linear equations were $A_{550} = 20.6c - 0.0044$, $R = 0.9986$. The concentration of $O_2^{\cdot -}$ can be calculated by the concentration of the formed ferrocyanochrome c according to the above reaction formula⁵².

Acknowledgements

This work was supported by Jiangsu Collaborative Innovation Center of Biomedical Functional Materials, National Natural Science Foundation of China (21571104, 2015M580446), Natural Science Foundation of Jiangsu Province of China (BK 20131396), and the Priority Academic Program Development of Jiangsu Higher Education Institution.

Author Contributions

C.M. and M.W. proposed and supervised the project. X.S. and F.W. wrote the main manuscript text and discussed the results and experimental conditions with all other authors. X.S., Q.W. and L.M. designed and set up the experimental setup. X.S., Q.W., W.X. and Y.L. carried out the experiments. X.S., W.X. and S.F. designed and carried out the data analysis. All authors have given approval to the final version of the manuscript.
